Visual memory involves the ability to store and retrieve previously experienced visual sensations and perceptions when the stimuli that originally evoked them are no longer present. That is, the person must be capable of making a vivid visual image in his mind of the stimulus, such as a word, and once that stimulus is removed, to be able to visualize or recall this image without help.

In visual systems, orientation selectivity is a well-known biological function of the primary visual cortex that is necessary for encoding of visual images (1, 39). In the primary visual cortex, neurons respond preferentially to edges with a particular orientation of input patterns, which is ascribed to the feed-forward filtering function that causes weight enhancement near the preferred ...

Neuronal activity in the PFC demonstrates visual short-term memory correlates by exhibiting sustained changes, often elevation, but sometimes suppression, during the retention interval of short-term memory tasks (e.g., Fuster & Alexander, 1971; Miller et al., 1996; Shafi et al., 2007 ). Visual recognition memory is also apparent in the PFC primarily exhibiting match enhancement while some cells exhibit match suppression (e.g., Miller et al., 1996 ).

The Effect of Visual Memory. Women reveal better visual memory in the identification and recognition of human faces, as shown by research into the effect of memory on the psychological perception of the face over different periods of time (5, 10, and 30 min). The ability to remember a face decreases significantly as more time elapses between exhibition of the face and the request to identify and recognize it at a later stage.

The visual and auditory memory literature has traditionally divided memory into separate component systems such as sensory memory and short-term, long-term, and working memory (Cowan, 1995, 2001, 2008; Linden, 2007). Sensory memory refers to the registers for veridical, modality-specific representations that provide the first memories of inputs to each of our senses.
